INTRODUCTION

Purpose and Intended Use

This report is intended to assist planners in meeting their needs for population projections. It provides assistance in understanding the methods used, their advantages and disadvantages, and their utility.

Description

This report provides a collection of population projections for a portion of the southwest region of Alberta in which the urban, rural and specialized municipalities are members of the Oldman River Regional Services Commission (ORRSC). Three population projection methods are used. The report is made up of three different divisions: a textual discussion of base data, methodologies, and basic assumptions; the projected population statistics; and a summary.

GENERAL CHARACTERISTICS OF PROJECTIONS

The knowledge of possible directions of population change can aid in assessing future requirements for land, services and facilities. Using population projections, planners can formulate the necessary strategy to cope with population change and its effects on a municipality.

Population projections have been defined as the numerical outcome of a set of assumptions made about future trends, usually with reference to trends of the past. Projections are conditional; they show what a population would be if these assumed trends were to occur.

Any projection must be carefully reviewed by evaluating the method used and the specific assumptions within each method. Some of the factors to be considered in evaluating population projections are:

- Population projection methods are only as accurate as the initial data.
- In general, the smaller the initial population, the greater the error to be expected.
- The further into the future the projections are carried, the less reliable the projection.
- The accuracy of the projected results also relies on how representative the base time period is of the typical growth experienced by the municipality.
- There are various forces affecting population change. The most common ones are migration, birth, death, fertility, social, economic and political. Methods incorporating the greatest number of these elements in the projections will result in figures closer to reality.

BASIC ASSUMPTIONS

Basic assumptions made by the methods utilized in this report are:

- Input data source: Census of Canada 2001, 2006, 2011, 2016 and 2021. (see Table 1 for data used in projections)
- Data reflects random rounding at the cohort level only.
- Where feasible, figures have been adjusted to reflect significant boundary changes due to annexation or incorporation of hamlets. This includes the following specifically:
 - The incorporation of Grassy Lake into the M.D. of Taber in 1994. Therefore census population after 1994 for the M.D. of Taber are inclusive of Grassy Lake and no census data for Grassy Lake specifically.
 - The change of the M.D. of Ranchland from the I.D. No. 6 in 1995. Population census data for the M.D. of Ranchland in 1991 contains population from what

Table 1 – Base Population Data (used in projections)

was actually I.D. No. 6. I.D. No. 6 then became the M.D. of Ranchland in 1995, upon which boundary changes were also made.

- The Crowsnest Pass is a specialized municipality that was formed in 1979 through the amalgamation of Blairmore, Bellevue, Coleman, Frank and a portion of I.D. No. 5. Upon the creation of the M.D. of Ranchland in 1995, the Crowsnest Pass also incorporated a portion of I.D. No. 6.
- The incorporation of Granum into the M.D. of Willow Creek as a hamlet in 2020. Beginning in 2021, the Census of Population data for Willow Creek is inclusive of Granum.
- As changing economic, political and social forces are difficult to quantify and factor into a projection, they have not been included and are assumed to remain constant as in the base time period selected.
- The projection formulas have been unilaterally applied to all municipalities regardless of size.
- Projections are done at five-year intervals for a period of 25 years (2026, 2031, 2036, 2041, 2046).

Table 1 – Base Population Data (used in projections)

ORRSC REGION MUNICIPALITIES BASE POPULATION 2001-2021

MUNICIPALITY	YEAR	YEAR	YEAR	YEAR	YEAR	Population Change (%)
	2001	2006	2011	2016	2021	2016-2021
<i>Arrowwood</i>	196	221	188	207	188	-9.18%

ORSSC Region	89956	91291	95107	97930	102044	4.20%

Significant Non-ORRSC Municipalities within the ORRSC region.

City of Lethbridge	67374	74637	83517	92729	98406	6.12%
Town of Coaldale	6008	6177	7493	8215	8771	6.77%
Town of Taber	7671	7591	8104	8428	8862	5.15%
County of Newell	7137	6862	7138	7524	7465	-0.78%

This table was last updated in 2022 following the release of the 2021 Census of Population data in February 2022.

* Granum was incorporated into the M.D. of Willow Creek in 2020

** Grassy Lake was incorporated into the M.D. of Taber in 1994

+ Population for M.D. of Taber after 1996 Census data includes Grassy Lake

++ Revised 2016 counts are provided for Nanton and County of Warner

~ Population for M.D. of Willow Creek for 2021 Census and subsequent years includes Granum

*** M.D. of Ranchland 1991 census population is from I.D. No. 6,

which became M.D. of Ranchland, including slight boundary changes, in 1995.

Statistics Canada Census information from 1991, 1996, 2001, 2006 & 2011

*+ The Crowsnest Pass is a specialized municipality that was formed in 1979 through the amalgamation

of Blairmore, Bellevue, Coleman, Frank and a portion of I.D. No. 5. Upon the creation of the

M.D. of Ranchland in 1995, the Crowsnest Pass also incorporated a portion of I.D. No. 6.

POPULATION PROJECTIONS BY METHOD

The methods used can be classified into two general categories:

1. **Mathematical Extrapolation**, where a straight line is used to extend a population trend of the past into the future.
2. **Cohort Component Method**, where the population is split age and sex groups and the computations show the results of the interaction of fertility, mortality, and mobility.

1. Mathematical Extrapolation

Two mathematical extrapolation methods have been used: the Arithmetic and the Logarithmic Straight Line. One may be more suitable than the other depending on which line fits the past population trend best.

Advantages and Disadvantages

It is the simplest and quickest way to obtain a projected population.

It can lead to unreasonable population projections, as the basic assumption of a particular rate of growth continuing in the future would mean fast growing populations would have larger and larger gains, while declining populations would ultimately result in no population, or mathematically displaying a negative population (for example, Coutts and Glenwood).

Although unlimited increase or decrease can be controlled with logical implications such as in a logistic curve, it still has little correspondence with the forces of population change, and there is generally no useful meaning to the concept of an upper limit to population change.

Utility

Provides a quick description of underlying growth or decline in a population, without any further analysis.

Generally useful only for a short range (5 years) and very long range (50+ years) projections where no age and sex details are needed.

Plotting the information on a graph would help determine whether an arithmetic or logarithmic line would provide the best description of the trend.

ARITHMETIC STRAIGHT LINE TREND

Method

Fits a straight line trend by the method of least squares to a quinquennial series of population values (2001 to 2021) and projects that trend to the year 2046. For detailed calculations see Appendix A.

Specific Assumptions

Population changes by a regular amount in each time period and all else remains equal. For example: Milo will continue to increase by 3.3 people every 5 years, and Claresholm will continue to increase by 44.4.

Projected Data See Table 2 for Arithmetic Straight Line Projections for each of the 43 municipalities in the region.

The equation: $Y_t = a + bx$

Y_t = pop. at time t
a = intercept
b = slope
x = time

Table 2 – Arithmetic Straight Line Projections

LOGARITHMIC STRAIGHT LINE TREND

Method

Describes the percentage rates of change taking place in a quinquennial series of population values (2001 to 2021) and extrapolates the population to the year 2046. For calculations see Appendix B.

Specific Assumptions

Populations increase or decrease at a constant percentage rate and all else remains equal. For example, Barnwell will continue to increase by 15.9 percent in population every five years and Coalhurst will continue to increase by 18.9 percent.

Projection Data

See Table 3 for Logarithmic Straight Line Projections for each of the 43 municipalities in the region.

The equation: $\text{Log}Y_t = a+bx$ Y_t = pop. at time t
 a = intercept
 b = slope
 x = time

* Granum was incorporated into the M.D. of Willow Creek in 2020										
** Grassy Lake was incorporated into the M.D. of Taber in 1994										
+ Population for M.D. of Taber after 1996 Census data includes Grassy Lake										
++ Revised 2016 counts are provided for Nanton and County of Warner										
~ Population for M.D. of Willow Creek for 2021 Census and subsequent years includes Granum										
*** M.D. of Ranchland 1991 census population is from I.D. No. 6, which became M.D. of Ranchland, including slight boundary changes, in 1995.										
+ The Crowsnest Pass is a specialized municipality that was formed in 1979 through the amalgamation of Blairmore, Bellevue, Coleman, Frank and a portion of I.D. No. 5. Upon the creation of the M.D. of Ranchland in 1995, the Crowsnest Pass also incorporated a portion of I.D. No. 6.										

2. Cohort Component Method

Advantages and Disadvantages

It is considered the most reliable of the available methodologies because it makes better use of the available data and tested demographic theory. For example, it takes into account the elements of fertility, mortality, and mobility.

It provides unique flexibility in projecting population as it allows for planned change and for local changes not systematically included in the calculations. Thus, each element: migration, fertility, birth and death ratios may be changed as desired.

As with all population projections, the component method can produce unreasonable results if the base time period was one of unusually strong or weak growth, or if the projection is applied too far into the future.

Again, the smaller the population, the greater the possibility of error.

The sum of separately projected components, such as age and sex groups, is generally more reliable as a projection of total population than a projection of the single aggregate for periods of 10 to 40 years.

Utility

Useful where projections are needed by age and sex groupings.

Provides the flexibility of altering migration rates due to anticipated or assumed changes in economic conditions.

GENERAL COHORT SURVIVAL

Method

The starting point is the 'age-sex' distribution of the population at the chosen census period (2021 Census, Statistics Canada). The 5-year provincial age and sex-specific survival rates for 2015-2019 (Alberta Health, Analytics and Performance Reporting Branch) and Census Division age-specific fertility rates for 2015-2019 (Statistics Canada & Alberta Vital Statistics) are applied to the population and held constant for the duration of the projection period. Migration is noted on the basis of the number of net migrants in the time period and is also held as a constant. Computations are usually by five-year age groups with projected results in five-year intervals.

Special procedures are required to obtain the population under five years of age in the projected periods (2026, 2031, 2036, 2041, 2046). For example, to determine the number of births and survivors between 2021 and 2026 in the 0-4 age group, the number of females in each of the childbearing age groups (15-49) are multiplied by the appropriate quinquennial fertility rate. The result is multiplied by the appropriate survivorship rate. This accounts for the number of children born between 2021 and 2026. To allocate the children to male or female categories, the Alberta Provincial Birth rate of 51 percent male to 49 percent female is used. These figures represent the number of children that would appear in the 2026 Census if natural increases were all that influenced population growth. If the actual 2026 figures are different, one can reasonably assume that in-migration or out-migration has occurred.

To arrive at the projected migration rates, past trends are used. Three options for growth are provided. The first uses the last five years for the historical base period. The actual 2016 population is projected to 2021 and then compared with the actual 2021 figures to arrive at a net migration factor for each age group.

As research has shown increasing the base period from 5 to 10 years increased the accuracy of 10, 20, and 30-year projections, a second alternative migration factor is provided. Migration rates are calculated for the 2011 - 2016 period and then averaged with the

2016-2021 rates, resulting in an option for growth based on the last 10 years.

Increasing the historical base to 20 years (2001 to 2021), can bring further improvements in accuracy in many cases, and provides the third option for growth.

Given the instabilities of growth rates and the tendency for extreme rates to moderate, the strategy of averaging migration rates seems to offer an improvement over using rates from the most recent period. Yet, the average rates do not necessarily offer the best projection strategy for specific places. When making projections for a few places, the analyst should at least try to decide which period's rates are the best indicator of the future. What led to past changes in the rates, and how might they change again? Which observed rates might best indicate the future? Another useful option is to compare both average and most recent rates. Comparing the numbers identifies places where growth has been unstable, and where more inquiry and thoughtful forecasts might be worthwhile.

Specific Assumptions

As birth and death rates are not consistently available by municipality, the provincial figures have been used and held constant throughout the projected period.

A migration rate unique to each municipality, once calculated, has been held constant throughout the projected period.

The population of the specific age group category of each census period (2001, 2006, 2011, 2016, 2021) was rounded to the nearest 5 in the census. Therefore the information input for the 5, 10 and 20 year cohort projections was input at 5 person rounded intervals. However, the resulting projections produced numbers that were not rounded.

Municipalities that display a negative population projection are assumed to have a population of 0 as no population can be negative

people. However, the negative number has been used in order to properly indicate the trend that has occurred.

SUMMARY

It is important to note that, although projections relate to the future, they depend on the extension of past trends with no reference to actual data during the projection period. They can sometimes be viewed as mechanical and unrealistic. However, the element of judgement and reasoning is essential in choosing the best projection for planning purposes.

When the user wants to know what the future population of a municipality will be, this report supplies a starting point. Once the municipality has been selected, the projection methods must be carefully evaluated, as well as the specific assumptions established within the methods. Further calculations altering assumptions in any of the methods can still be done quickly and simply. For example, if the fertility rate used in the cohort component method is not high enough, a simple recalculation on the computer can yield more applicable results.

A comparison of negative or positive population trends throughout the ORRSC region (numbers in the tables below do not include the City of Lethbridge, the Town of Coaldale, the Town of Taber or the County of Newell, as they are not ORRSC members) have been indicated below for the past 5 census periods (2001, 2006, 2011, 2016, 2021) using both the Arithmetic Projection and the Logarithmic Projections. The Cohort method was not indicated in the tables below because the method used looks at 5, 10, 20-year periods as a whole and not individual census periods. The following points have been noted:

**Table 4 –
Summary of Arithmetic Straight Line Projections**

No. of Municipalities that:	2021-2026	2026-2031	2031-2036	2036-2041	2041-2046
Gain in Population (Arithmetic)	23	24	24	26	26
Loss in Population (Arithmetic)	16	14	14	13	12
Remain the same	-	1	1	-	1

**Table 5 –
Summary of Logarithmic Straight Line Projections**

No. of Municipalities that:	2021-2026	2026-2031	2031-2036	2036-2041	2041-2046
Gain in Population (Logarithmic)	23	23	24	26	26
Loss in Population (Logarithmic)	16	15	15	13	13
Remain the same	-	1	-	-	-

The data from Table 4 shows that the arithmetic straight line projections from 2021 - 2046 estimate between 23 - 26 municipalities in the ORRSC region gaining population, while an estimated 12-16 municipalities will lose population. According to Table 5, using the logarithmic straight line projection, a projected 23 - 26 ORRSC municipalities will experience a gain in population between 2021 and 2046. During this same time period, using the same projection

method, an estimated 13 - 16 ORRSC municipalities will experience a loss in population.

In the last 20 years, 9 of the 43 municipalities showed a positive population growth in every 5-year period. The Village of Coutts showed negative growth every 5 years over the last 20. In the remaining 33 municipalities, the projection results vary between positive and negative growth through various 5-year census periods, but many have experienced more positive overall growth than negative. This is a direct result of a fluctuating population trend. On the whole, projections based on a 20-year trend reflect the best-case scenario, i.e. the highest gains and least losses.

In conclusion, population projections should be regarded as flexible guides for the future requiring judgment, reasoning and constant revision. Changing conditions in the municipality can alter the choice of projection to be used.
